

For each of the following situations (1 and 2):

(A) Define variables in a tabular format, as follows.

name      symbol      scale

scale = nominal, ordinal, or cardinal  
cardinal = interval or ratio scale.

nv = number of variables  
nt = number of terms  
A. score =  $3nv$   
B. score = nt  
C. score =  $2nv + 2$   
D. score = 1

(B) Using the symbols, write a general linear model relating the response variable to explanatory variable(s) and interaction terms (if appropriate).

(C) Complete the first two columns of the ANOVA table      source   df

(D) State the name of the analysis, from the following list.

t-test, one-way ANOVA, two-way ANOVA, three-way ANOVA  
paired comparisons, randomized blocks,  
hierarchical (nested) ANOVA  
regression, multiple regression,  
ANCOVA (at least 1 nominal and at least 1 cardinal scale explanatory variable)  
none of the above.

1. Daniel (*Biostatistics* 1995, p234) reported cell diameters ( $\mu\text{m}$ ) of 40 lymphocytes and 50 tumor cells obtained from biopsies of tissue from patients with melanoma. Do cancerous and non-cancerous cells differ in diameter ?      A=6 B=3 C=6 D=1

A. name   symbol   scale

C. source   df

B. \_\_\_\_\_ = \_\_\_\_\_ +  $\epsilon$       [3]

D. \_\_\_\_\_      [1]

2. Does birth weight depend on maternal smoking, controlled for gestation period and maternal weight ? Selvin (*Practical Biostatistical Methods*, 1995, Duxbury Press) reported birth weights of first infants (grams), gestation period (weeks), maternal smoking (0, 10-20, or  $\geq 40$  cigarettes per day), and maternal weight (kg) for 48 women over 40 years old. (Assume no interactive effects of explanatory variables on the response variable, as in multiple regression).

A=12 B=5 C=10 D=1

| A. | <u>name</u> | <u>symbol</u> | <u>scale</u> |
|----|-------------|---------------|--------------|
|    |             |               |              |

| C. | <u>source</u> | <u>df</u> |
|----|---------------|-----------|
|    |               |           |

B. \_\_\_\_\_ = \_\_\_\_\_ +  $\epsilon$  [3]

D. [1]

3a. Construct a one-way ANOVA table for which the total Sum of Squares is 100, 15% of this variability is due to treatment effects (control vs one treatment), and the sample size is 100. Be sure to compute MS and F-ratio .....[12]

3b. Explain how you would compute a p-value for the F-ratio in the table you have constructed, if the residuals were normal and independent, with fixed variance .....[2]

3c. Circle the effect (increase/decrease) of halving the sample size, in the ANOVA table you constructed (or any ANOVA table with the same model structure).....[3]

|                     |             |
|---------------------|-------------|
| increase   decrease | in MS error |
| increase   decrease | in F-ratio  |
| increase   decrease | in p-value  |

4a. Define a symbol for scutum width, in microns, of tick larvae on rabbit #4 (Sokal and Rohlf, 1995, p 208), then define a symbol for the observed (sample) mean and the true (population) mean.....[3]

4b. For the data on scutum width (6 values below) write the observed mean.  $\frac{\text{ }}{\text{(Symbol)}} = \frac{\text{ }}{\text{(Value)}} [1]$

4c. Write a probability statement for the 95% confidence limits around the true mean .....[2]

4d. What value of the t-distribution should you use for the 95% limits ? .....[1]

```
MTB > invcdf c10; SUBC> t 5.
0.0100 -3.3649
0.0250 -2.5706
0.0500 -2.0151
0.1000 -1.4759
0.9000 1.4759
0.9500 2.0151
0.9750 2.5706
0.9900 3.3649
```

4e. Compute the 95% confidence limits .....[2]

```
C6
376 344 342 372 374 360
```

```
MTB > describe c6
```

|    |         | N | MEAN   | MEDIAN | TRMEAN | STDEV | SEMEAN |
|----|---------|---|--------|--------|--------|-------|--------|
| C6 | ScWidth | 6 | 361.33 | 366.00 | 361.33 | 15.27 | 6.23   |
